

# **EVOLUTION OF SPECIES' CLIMATIC NICHE: LINKING BIOGEOGRAPHY AND MACROEVOLUTION**

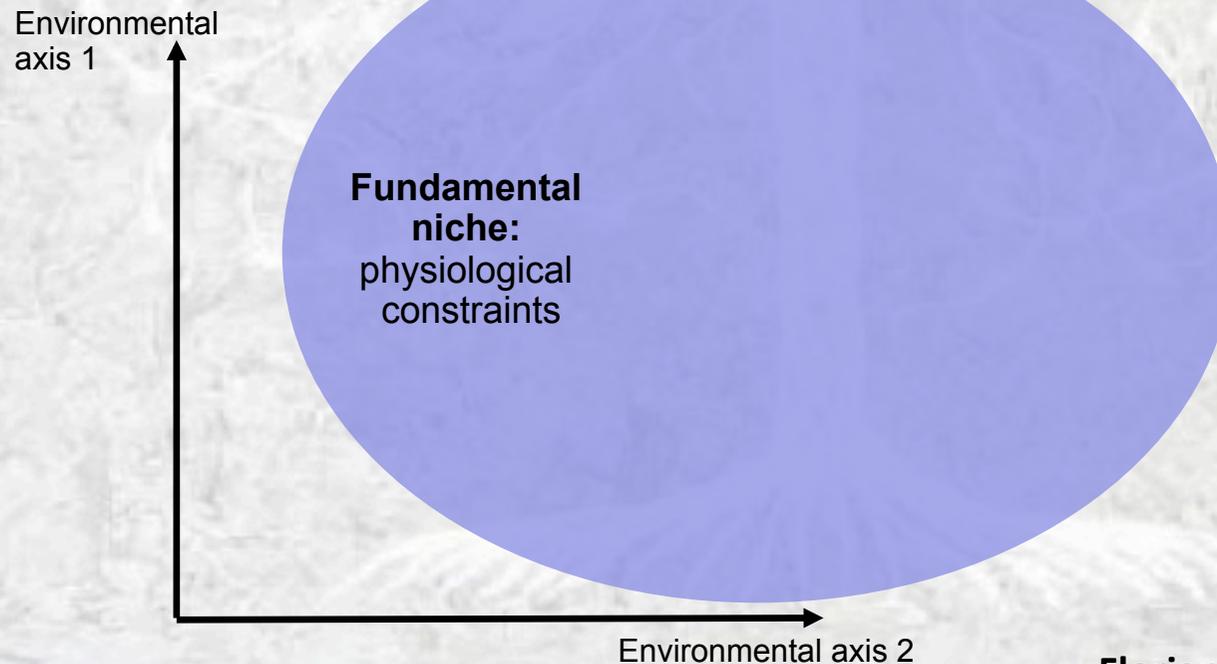

# WHAT IS THE NICHE?

- Set of environmental conditions in which populations of a species have strictly positive growth rate (Hutchinson 1957)

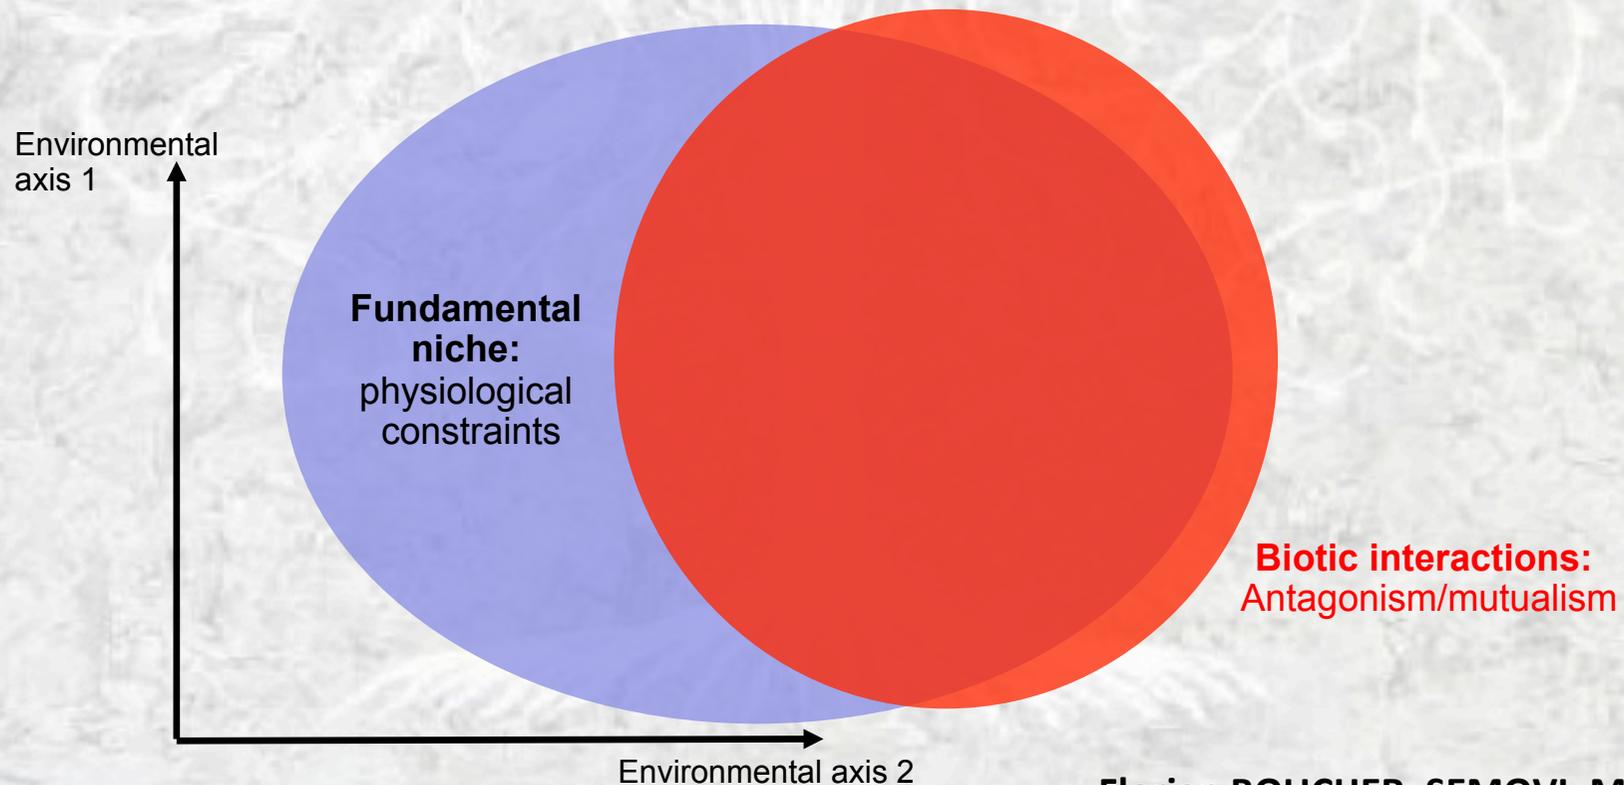

# WHAT IS THE NICHE?

- Set of environmental conditions in which populations of a species have strictly positive growth rate (Hutchinson 1957)
- **Fundamental** niche (abiotic conditions)  $\neq$  **realized** niche (biotic interactions + dispersal limitations)

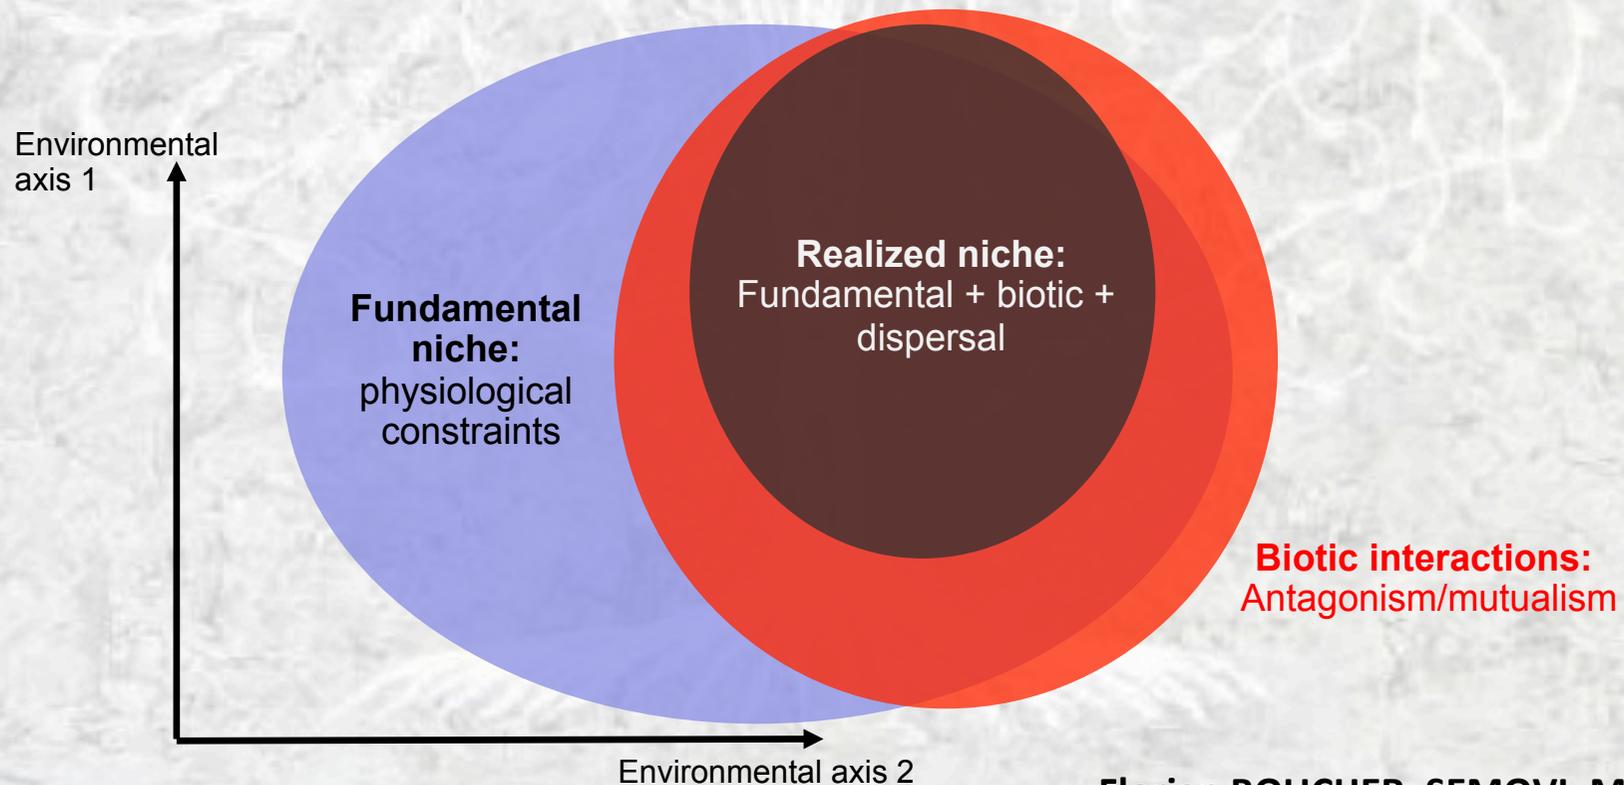

# WHAT IS THE NICHE?

- Set of environmental conditions in which populations of a species have strictly positive growth rate (Hutchinson 1957)
- **Fundamental** niche (abiotic conditions)  $\neq$  **realized** niche (biotic interactions + dispersal limitations)

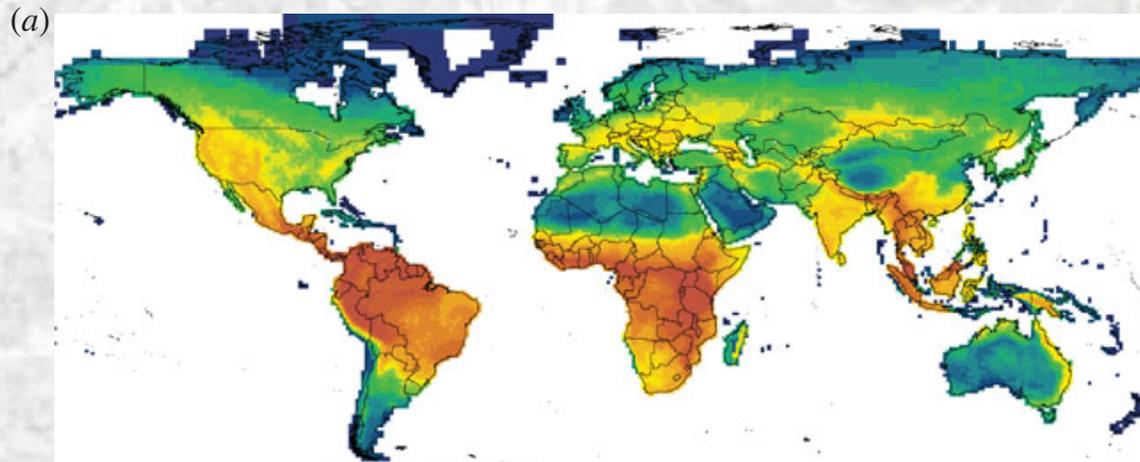

# WHAT IS THE NICHE?

- Set of environmental conditions in which populations of a species have strictly positive growth rate (Hutchinson 1957)
- **Fundamental** niche (abiotic conditions)  $\neq$  **realized** niche (biotic interactions + dispersal limitations)

# WHY DO WE CARE ABOUT NICHE EVOLUTION?

- **Fundamental question + consequences** on various questions:
  - past biogeographic patterns
  - diversity gradients
  - speciation ...

Latitudinal gradient in diversity in mammals, Buckley *et al.* 2010

# MODELING NICHE EVOLUTION OVER GEOLOGICAL TIMESCALES

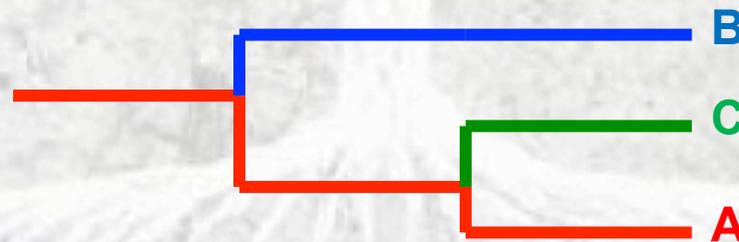

Use of the macroevolutionary toolbox for continuous traits:

- Niche represented as the **mean position** of a species over one (or several) environmental gradient(s) → huge simplification
- Species don't interact

# MODELING NICHE EVOLUTION OVER GEOLOGICAL TIMESCALES

Use of the macroevolutionary toolbox for continuous traits:

- Niche represented as the **mean position** of a species over one (or several) environmental gradient(s) → huge simplification
- Species don't interact
- **Phylogeny** gives us divergence times between species:

# THE NEUTRAL MODEL: BROWNIAN MOTION

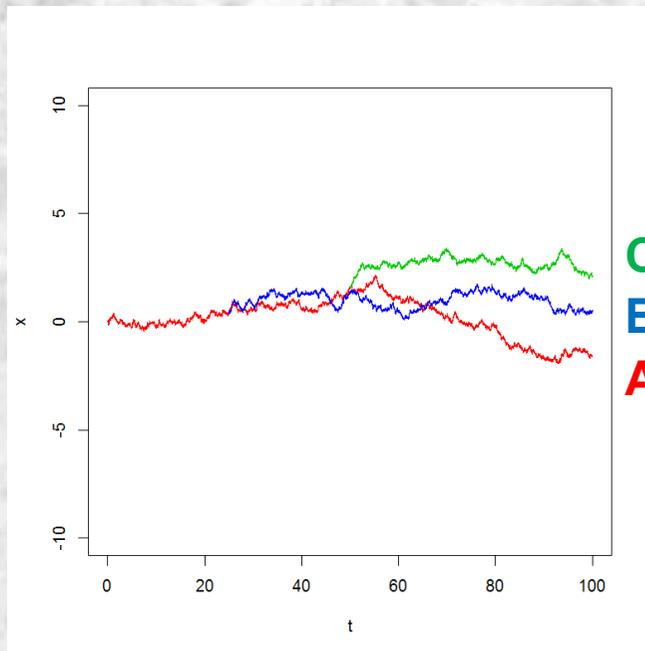

- Analogue of drift for geological timescales:

$$dX(t) = \sigma \cdot dt \cdot dW \quad , \quad \text{where } dW \sim N(0,1) \text{ (Wiener process)}$$

# THE NEUTRAL MODEL: BROWNIAN MOTION

- Analogue of drift for geological timescales:

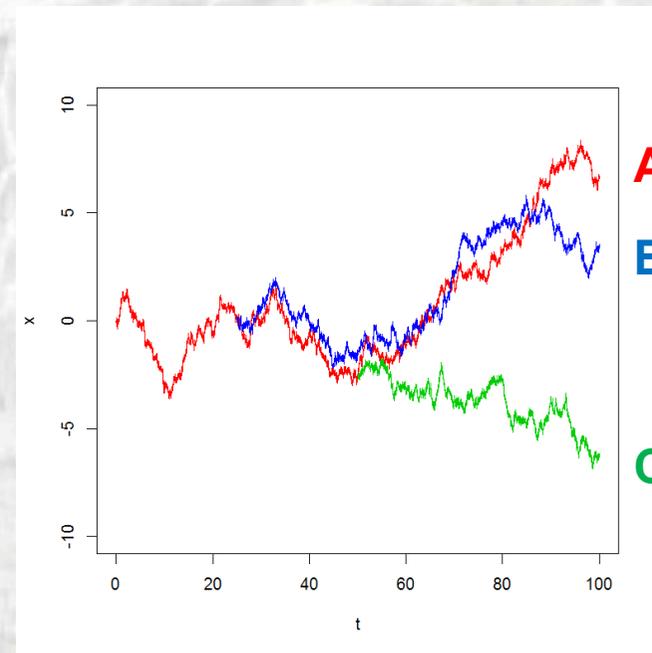

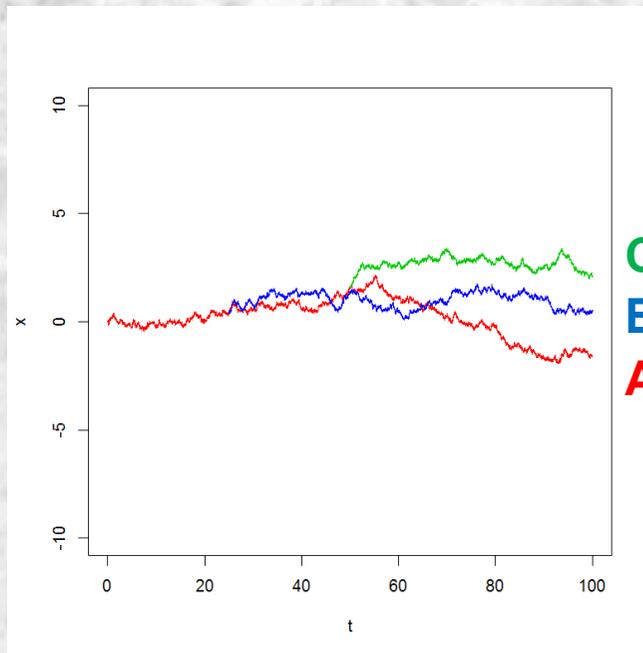

$$dX(t) = \sigma \cdot dt \cdot dW \quad , \quad \text{where } dW \sim N(0,1) \quad (\text{Wiener process})$$

# THE NEUTRAL MODEL: BROWNIAN MOTION

- Analogue of drift for geological timescales:

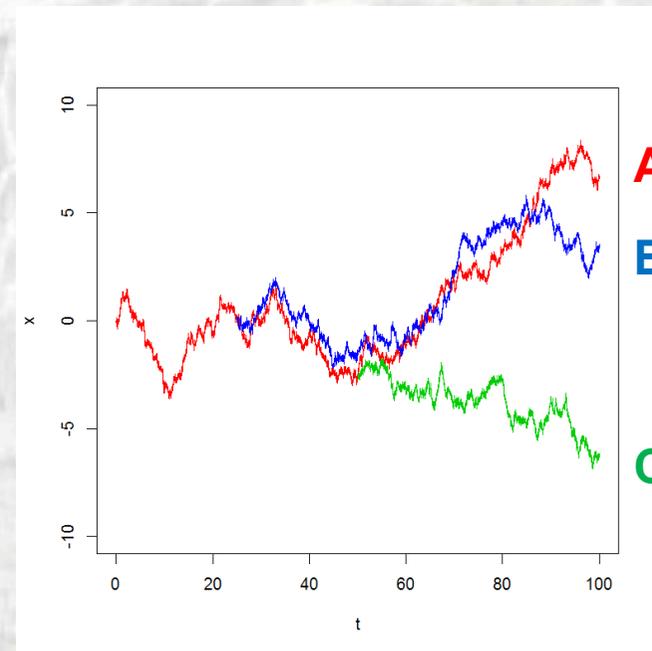

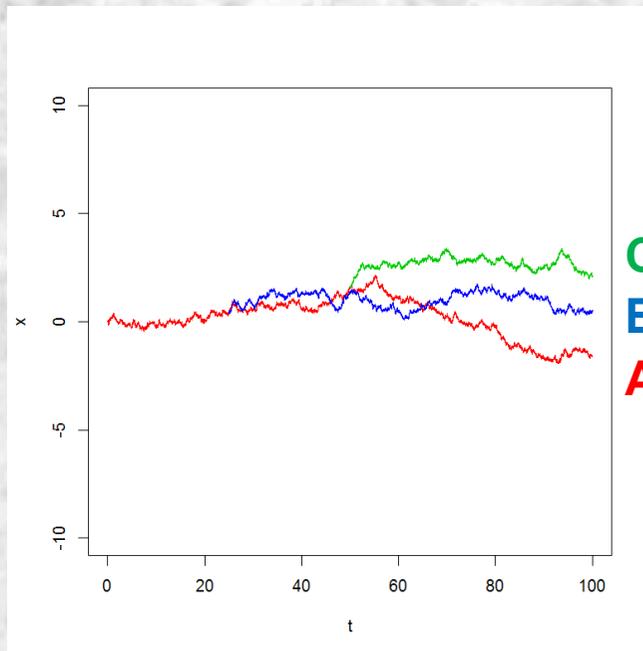

$$dX(t) = \sigma \cdot dt \cdot dW \quad , \quad \text{where } dW \sim N(0,1) \quad (\text{Wiener process})$$

# THE NEUTRAL MODEL: BROWNIAN MOTION

- Analogue of drift for geological timescales:

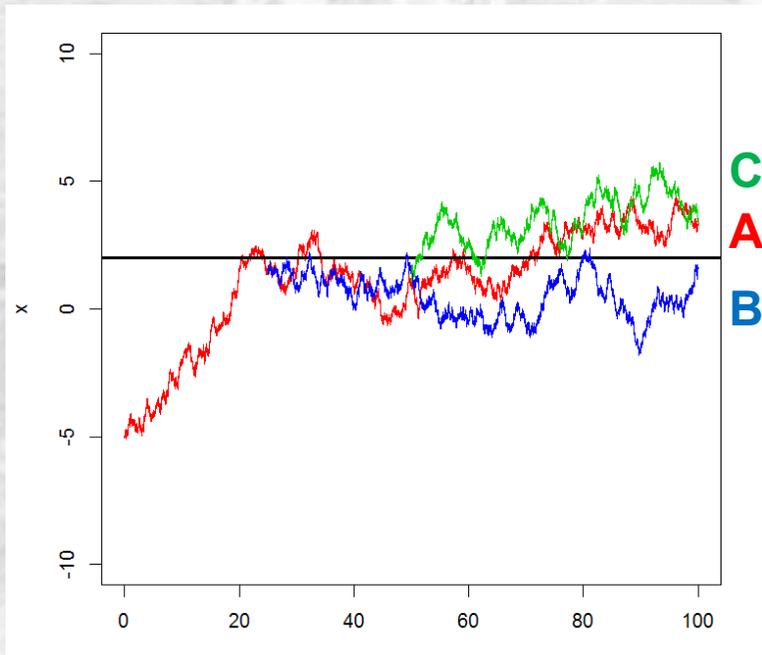

$$dX(t) = \sigma \cdot dt \cdot dW \quad , \quad \text{where } dW \sim N(0,1) \quad (\text{Wiener process})$$

- trait distance increases linearly with time since divergence (on average)
- **Fundamental** model in macroevolution, used everywhere!

# Two main deviations from Brownian Motion

- **Constraints** on niche evolution

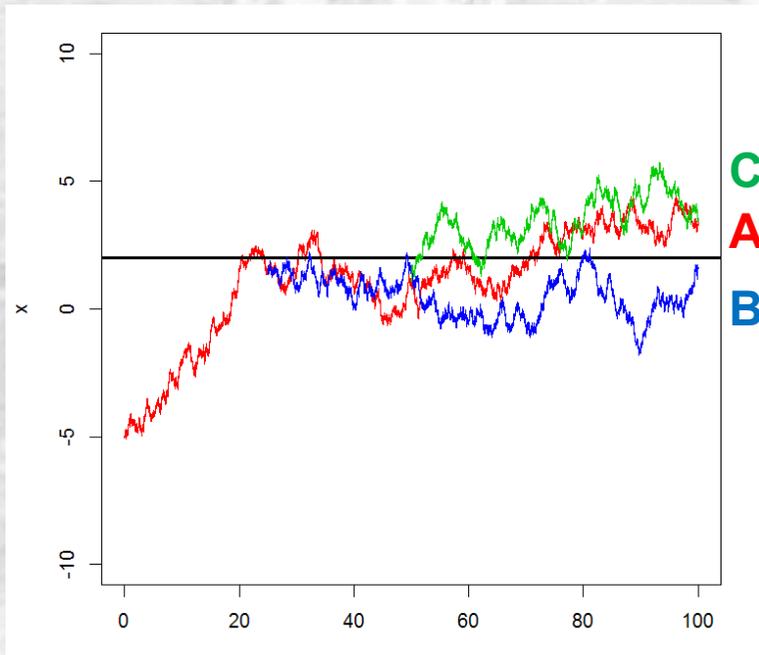

- Modeled using an Ornstein-Uhlenbeck process:

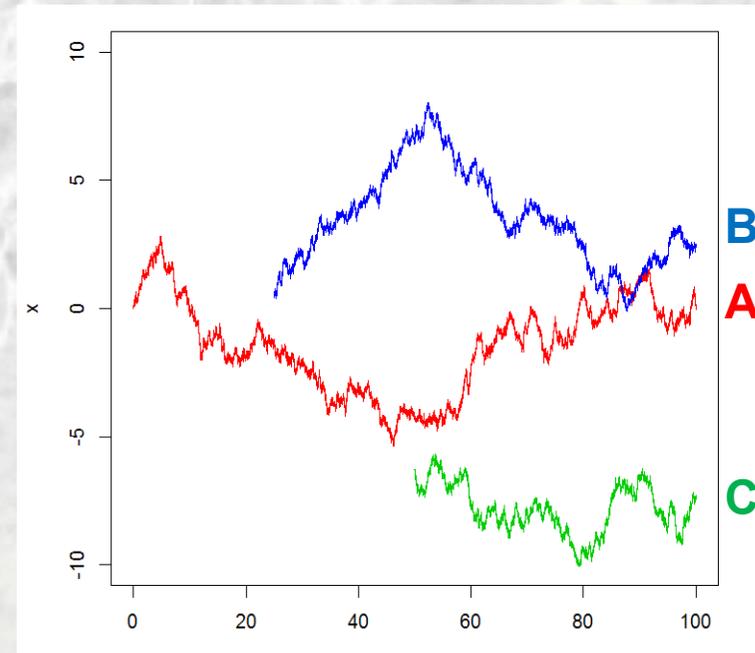

$$dX(t) = \alpha.(\mu - X(t)).dt + \sigma.dt.dW$$

# Two main deviations from Brownian Motion

- Constraints on niche evolution

- Punctualism

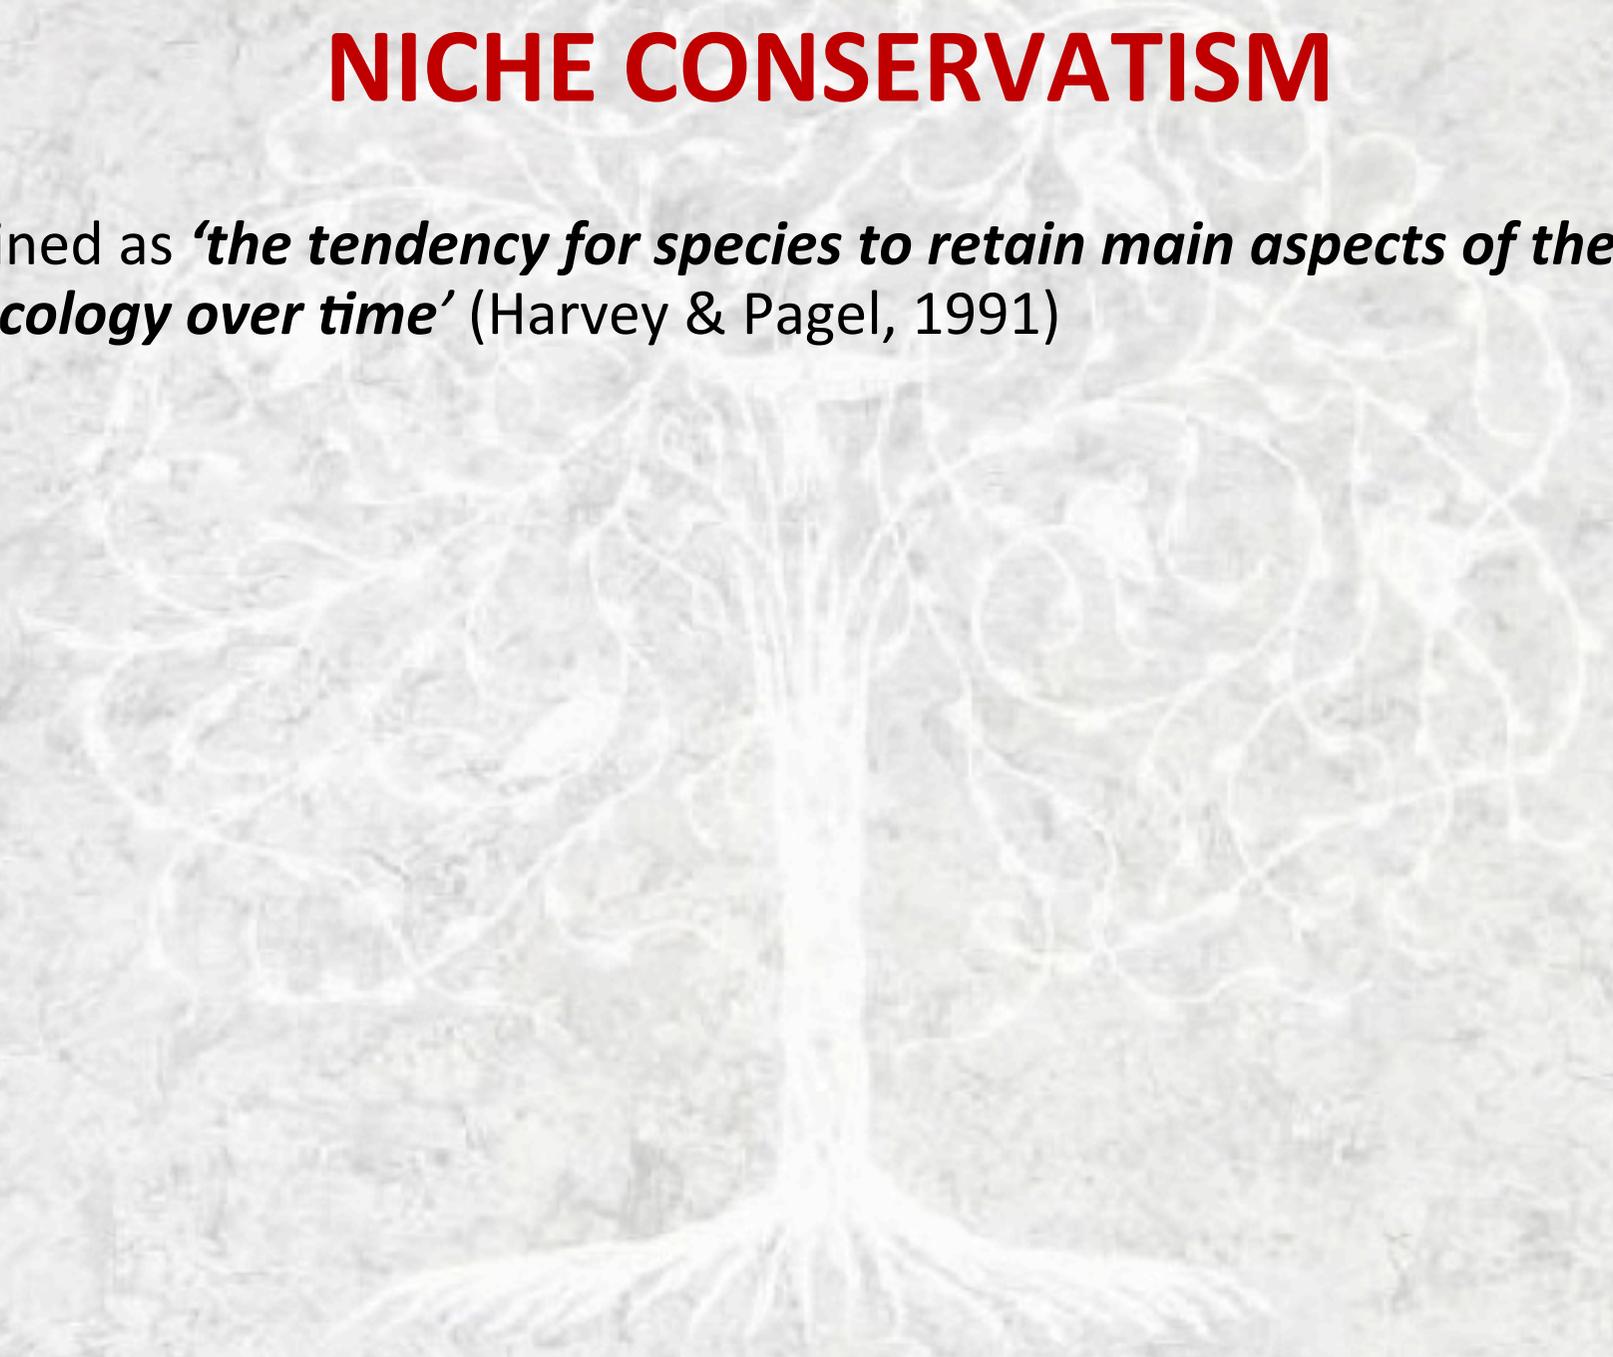

- Modeled using an Ornstein-Uhlenbeck process:

$$dX(t) = \alpha \cdot (\mu - X(t)) \cdot dt + \sigma \cdot dt \cdot dW$$

- Discrete shifts happen at speciation (Gould & Eldredge, 1979; Bokma 2008)

# A CENTRAL CONCEPT: PHYLOGENETIC NICHE CONSERVATISM

Defined as *'the tendency for species to retain main aspects of their ecology over time'* (Harvey & Pagel, 1991)

# A CENTRAL CONCEPT: PHYLOGENETIC NICHE CONSERVATISM

REVIEW AND SYNTHESIS

Niche conservatism as an emerging principle in ecology and conservation biology

Phylogenetic niche conservatism: what are the underlying evolutionary and ecological causes?

Michael D. Crisp<sup>1</sup> and Lyn G. Cook<sup>2</sup>

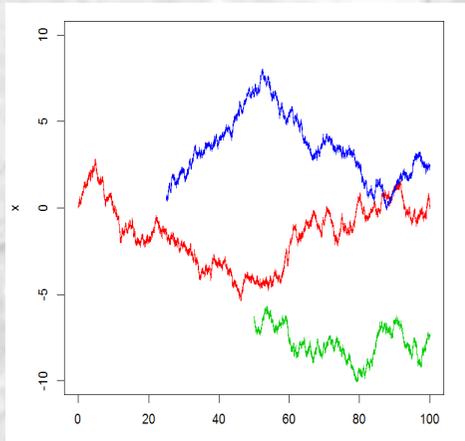

# Consensus emerging on how to test for Phylogenetic Niche Conservatism (PNC): model comparison

## **Brownian Motion:**

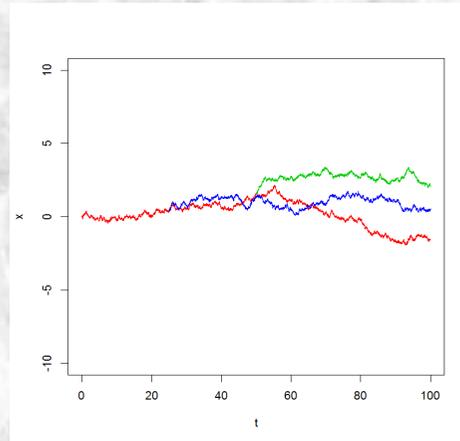

The neutral expectation,  
niche drifts

# Consensus emerging on how to test for Phylogenetic Niche Conservatism (PNC): model comparison

## **Punctualism:**

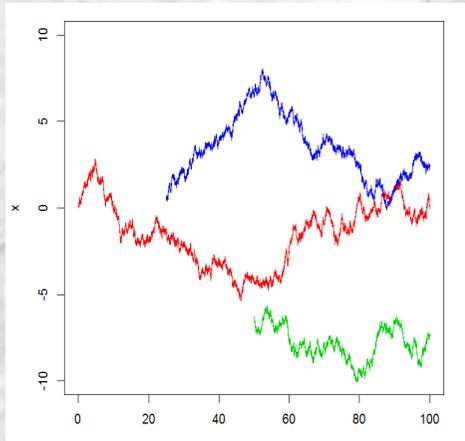

Niche is labile or is even responsible for speciation (divergent selection)

## **Brownian Motion:**

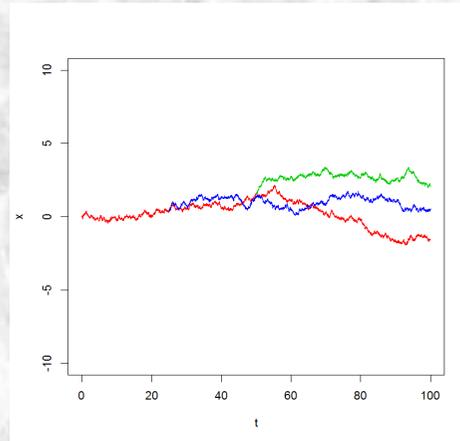

The neutral expectation, niche drifts

# Consensus emerging on how to test for Phylogenetic Niche Conservatism (PNC): model comparison

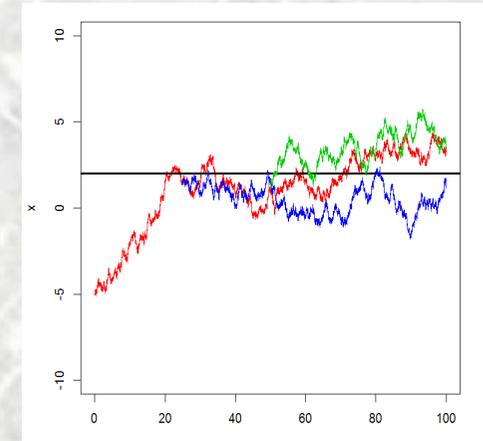

## **Punctualism:**

Niche is labile or is even responsible for speciation (divergent selection)

## **Brownian Motion:**

The neutral expectation, niche drifts

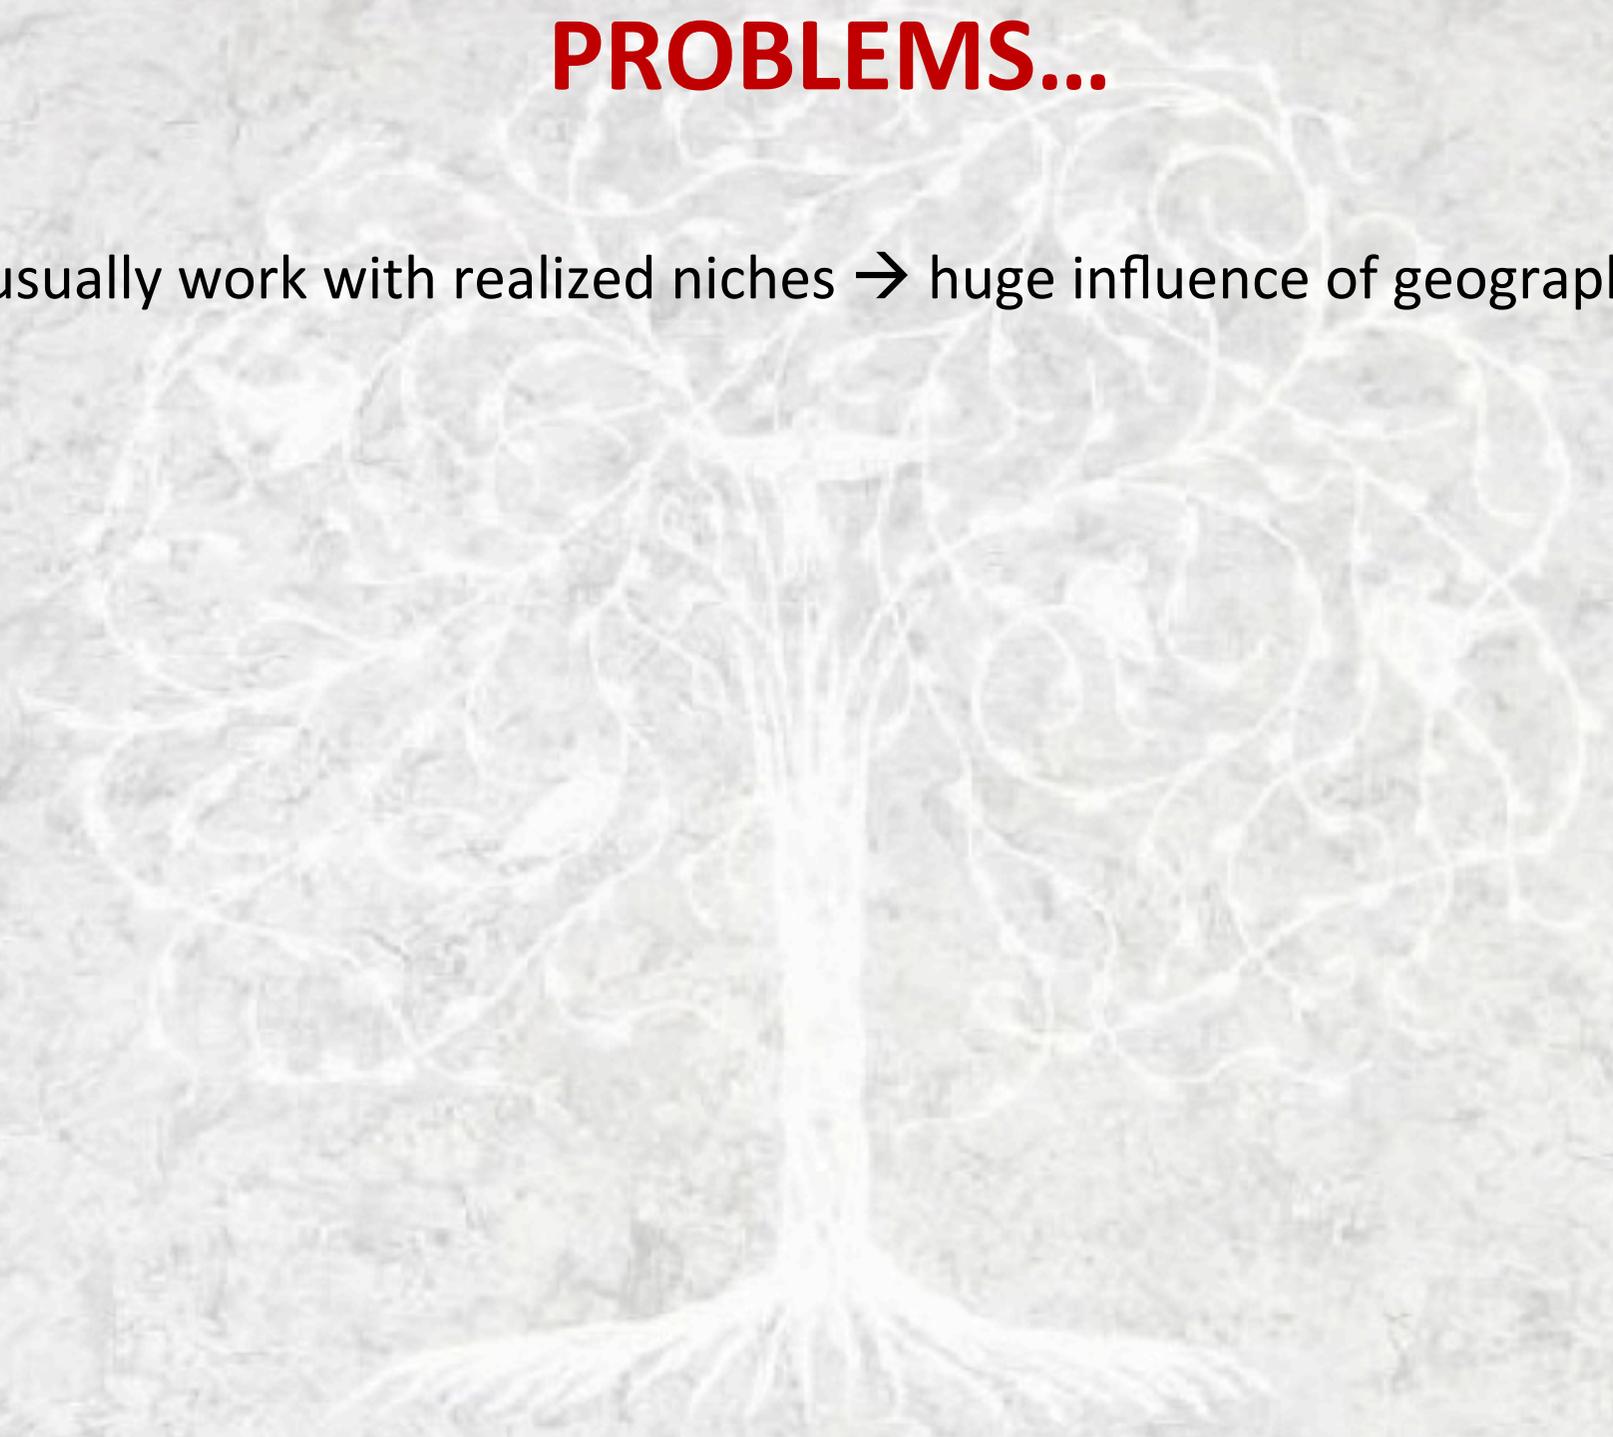

## **OU:**

Stabilizing selection on the niche → PNC!

# PROBLEMS...

We usually work with realized niches → huge influence of geography

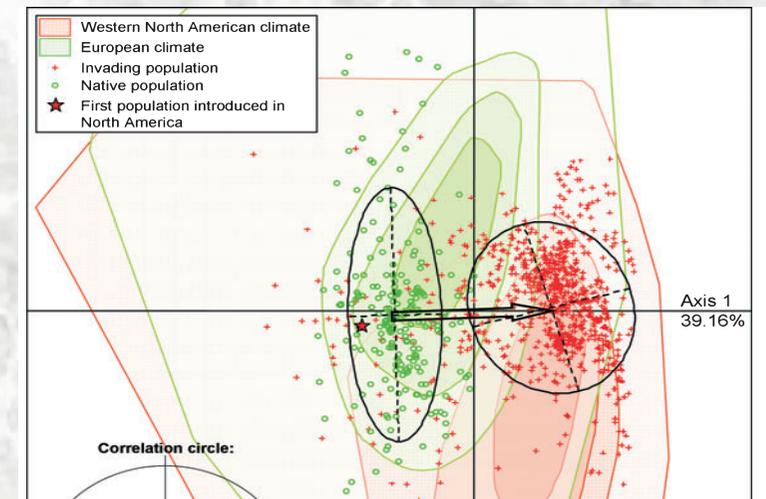

# PROBLEMS...

We usually work with realized niches → huge influence of geography

- **Niche shifts exist** (e.g. invasive species, long-distance dispersal)

Introduction of the Spotted Knapweed in Northern America,  
Broennimann *et al.* 2007

WHAT WOULD BE THE NEUTRAL EXPECTATION FROM A  
BIOGEOGRAPHIC POINT OF VIEW?

# GENERAL MODELLING STRATEGY

**RATIONALE:** 1) simulate a with a **very simple model**, where we make the least assumptions possible and then 2) see what patterns it produces

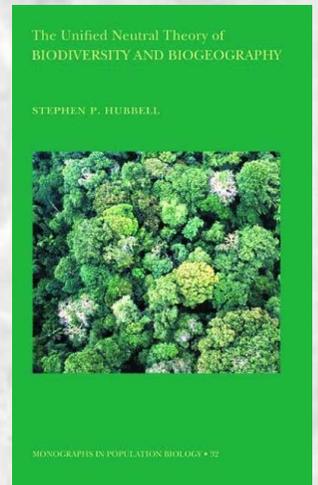

# GENERAL MODELLING STRATEGY

**RATIONALE:** 1) simulate a with a **very simple model**, where we make the least assumptions possible and then 2) see what patterns it produces

1) Simulate climatic niches evolving according to **Neutral Biodiversity Theory (NBT, Hubbell 2001)**

→ all individuals are functionally equivalent, whatever the species they belong to

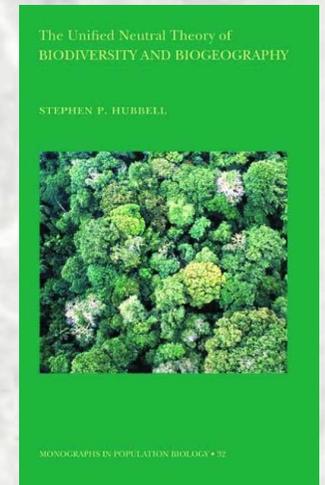

# GENERAL MODELLING STRATEGY

**RATIONALE:** 1) simulate a with a **very simple model**, where we make the least assumptions possible and then 2) see what patterns it produces

1) Simulate climatic niches evolving according to **Neutral Biodiversity Theory** (NBT, Hubbell 2001)

→ all individuals are functionally equivalent, whatever the species they belong to

2) Compare the fit of different macroevolutionary models to the niches and trees produced: BM, Ornstein-Uhlenbeck, punctualism?

# Simulation from the Neutral Biogeography Theory

- Landscape (continent) = rectangle with boundaries (51x21 pixels) ; maximum 20 individuals per community (pixel)
- Initial state : central community filled with the ancestral species ; the rest is empty

# Simulation from the Neutral Biogeography Theory

- Landscape (continent) = rectangle with boundaries (51x21 pixels) ; maximum 20 individuals per community (pixel)
- Initial state : central community filled with the ancestral species ; the rest is empty
- Algorithm ( $\times 10^8$  steps):

Select an individual  
from the  
metacommunity

# Simulation from the Neutral Biogeography Theory

- Landscape (continent) = rectangle with boundaries (51x21 pixels) ; maximum 20 individuals per community (pixel)
- Initial state : central community filled with the ancestral species ; the rest is empty

- Algorithm ( $\times 10^8$  steps):

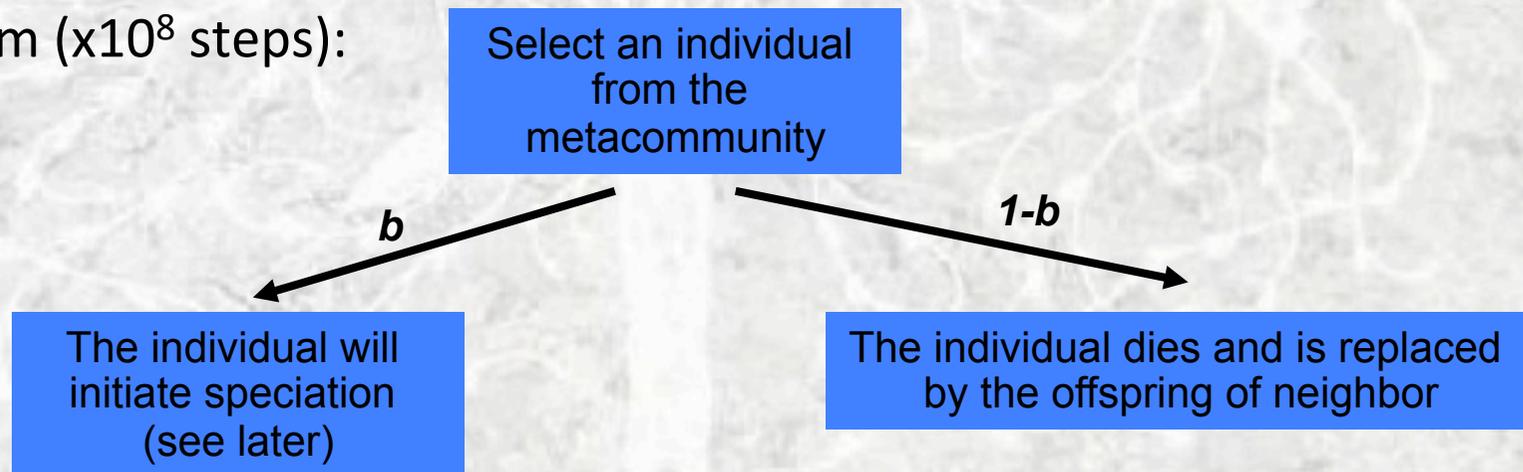

Select an individual from the metacommunity

*b*

The individual will initiate speciation (see later)

# Simulation from the Neutral Biogeography Theory

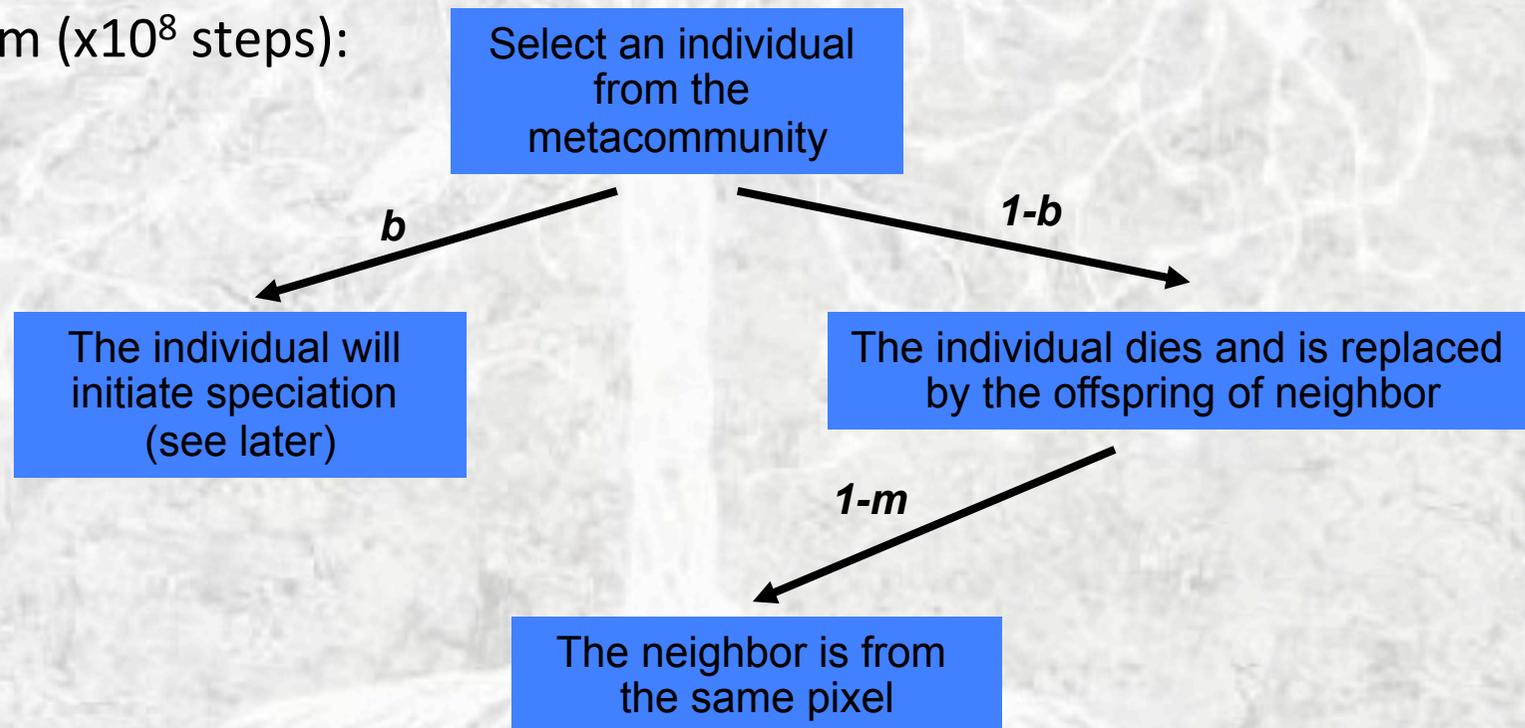

- Landscape (continent) = rectangle with boundaries (51x21 pixels) ; maximum 20 individuals per community (pixel)
- Initial state : central community filled with the ancestral species ; the rest is empty
- Algorithm ( $\times 10^8$  steps):

# Simulation from the Neutral Biogeography Theory

- Landscape (continent) = rectangle with boundaries (51x21 pixels) ; maximum 20 individuals per community (pixel)
- Initial state : central community filled with the ancestral species ; the rest is empty

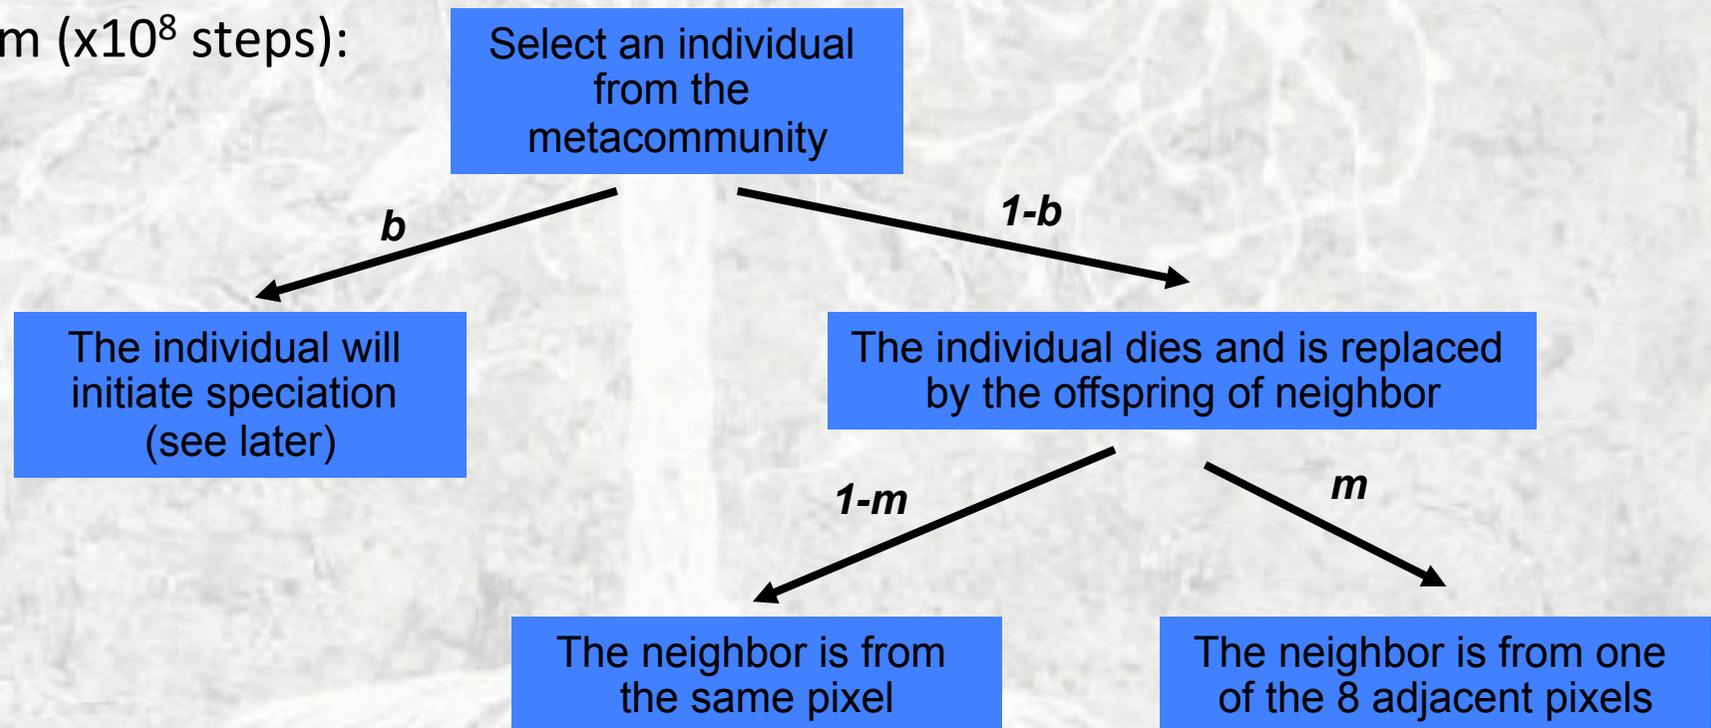

- Algorithm ( $\times 10^8$  steps):

# Simulation from the Neutral Biogeography Theory

- Landscape (continent) = rectangle with boundaries (51x21 pixels) ; maximum 20 individuals per community (pixel)
- Initial state : central community filled with the ancestral species ; the rest is empty

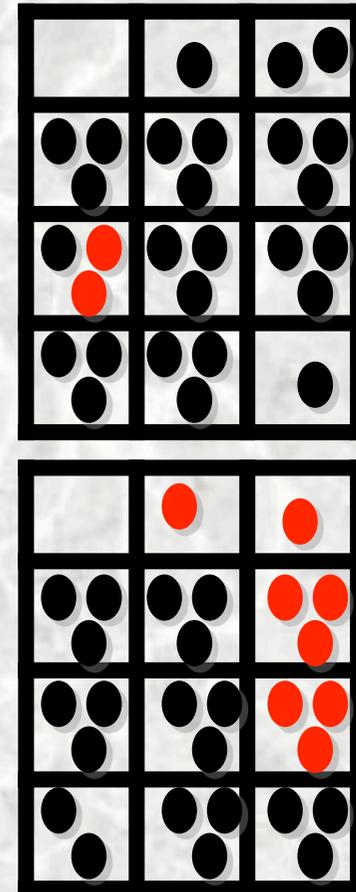

- Algorithm ( $\times 10^8$  steps):

# Simulation from the Neutral Biogeography Theory (2)

Two modes of speciation:

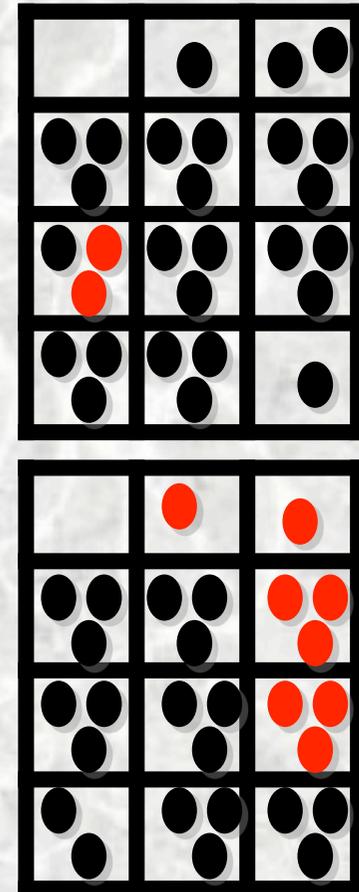

- **Random fission** (Hubbell 2001): a random fraction of conspecifics in the same pixel form the new species
- **Vicariance** (Pigot *et al.* 2010): a barrier cuts the species in two

# Simulation from the Neutral Biogeography Theory (2)

Two modes of speciation:

- **Random fission** (Hubbell 2001): a random fraction of conspecifics in the same pixel form the new species
- **Vicariance** (Pigot *et al.* 2010): a barrier cuts the species in two

The environment does not influence the process

→ **all species have the same fundamental niche**, but we measure their realized niches (mean latitudinal position)

# ANALYTICAL TREATMENT: ANAGENESIS

2 steps in the algorithm: death and reproduction (migration)

Equation for the evolution of the niche of one species, during anagenesis and before boundaries have been reached:

$$E(\text{Niche}(t + dt)) = \text{Niche}(t) \quad (1)$$

# ANALYTICAL TREATMENT: ANAGENESIS

2 steps in the algorithm: death and reproduction (migration)

Equation for the evolution of the niche of one species, during anagenesis and before boundaries have been reached:

$$E(\text{Niche}(t + dt)) = \text{Niche}(t) \quad (1)$$

$$\text{Var}_{\text{death}}(\text{Niche}(t + dt) - \text{Niche}(t)) = \frac{1}{K \times L \times l} \times \frac{N(t)}{(N(t) - 1)^2} \times \text{Var}(y_i(t)) \quad (2)$$

$$\text{Var}_{\text{reproduction}}(\text{Niche}(t + dt) - \text{Niche}(t)) = \frac{1}{K \times L \times l} \times \frac{N(t)}{(N(t) + 1)^2} \times \left[ \text{Var}(y_i(t)) + \frac{3}{4} \times m \right] \quad (3)$$

# ANALYTICAL TREATMENT: ANAGENESIS

2 steps in the algorithm: death and reproduction (migration)

Equation for the evolution of the niche of one species, during anagenesis and before boundaries have been reached:

$$E(\text{Niche}(t + dt)) = \text{Niche}(t) \quad (1)$$

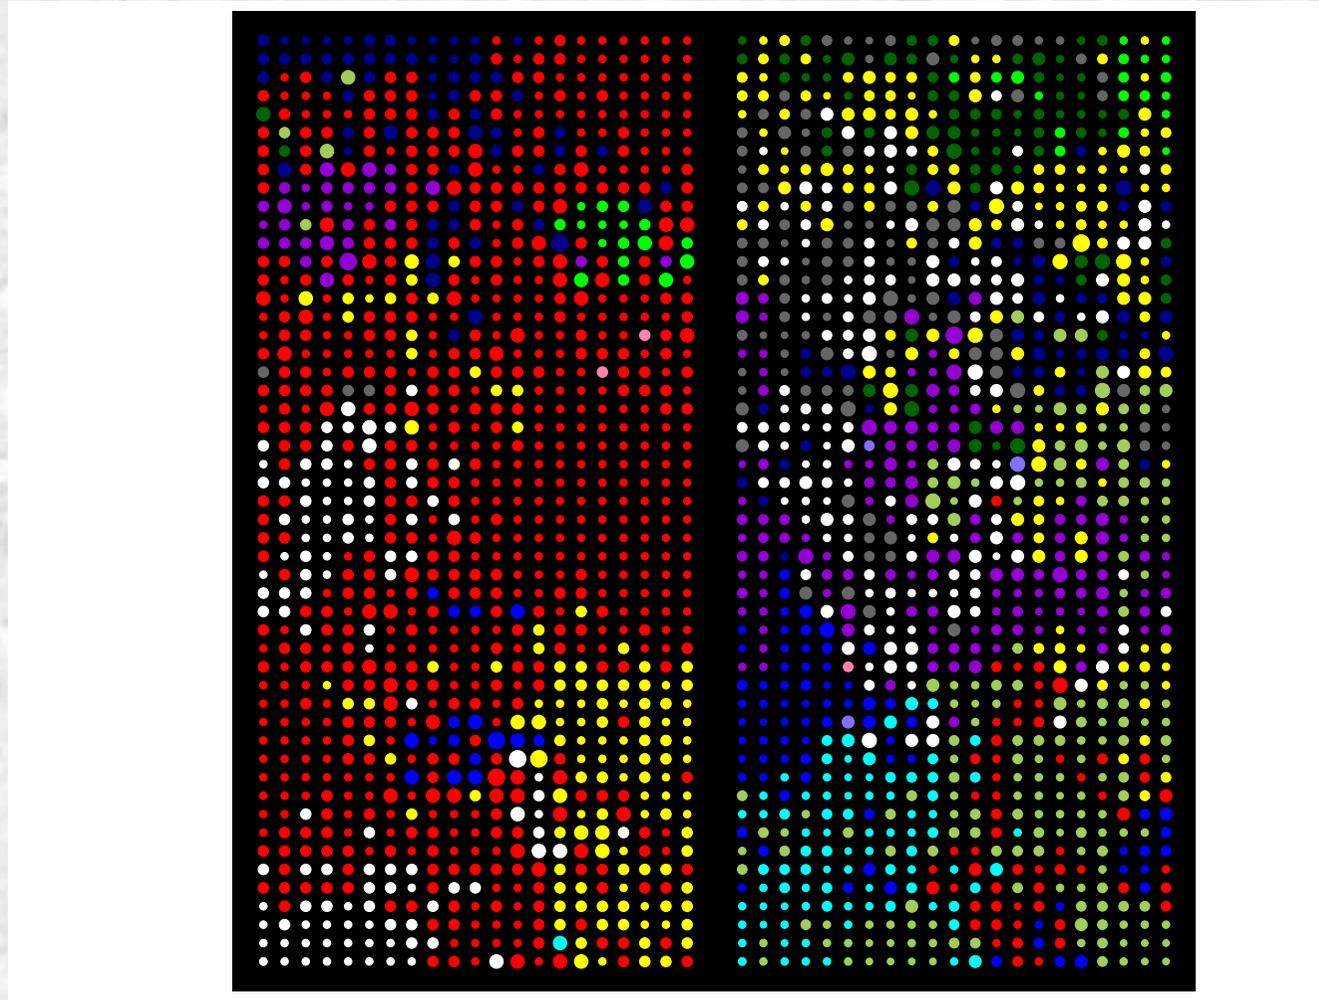

$$\text{Var}_{\text{death}}(\text{Niche}(t + dt) - \text{Niche}(t)) = \frac{1}{K \times L \times l} \times \frac{N(t)}{(N(t) - 1)^2} \times \text{Var}(y_i(t)) \quad (2)$$

$$\text{Var}_{\text{reproduction}}(\text{Niche}(t + dt) - \text{Niche}(t)) = \frac{1}{K \times L \times l} \times \frac{N(t)}{(N(t) + 1)^2} \times \left[ \text{Var}(y_i(t)) + \frac{3}{4} \times m \right] \quad (3)$$

→ niche follows **random steps** with no preferred direction (1), with size depending on migration rate, niche breadth and population size (2-3)

# ANALYSIS OF SIMULATION OUTCOMES

- 3600 simulations, parameters and mode of speciation vary:

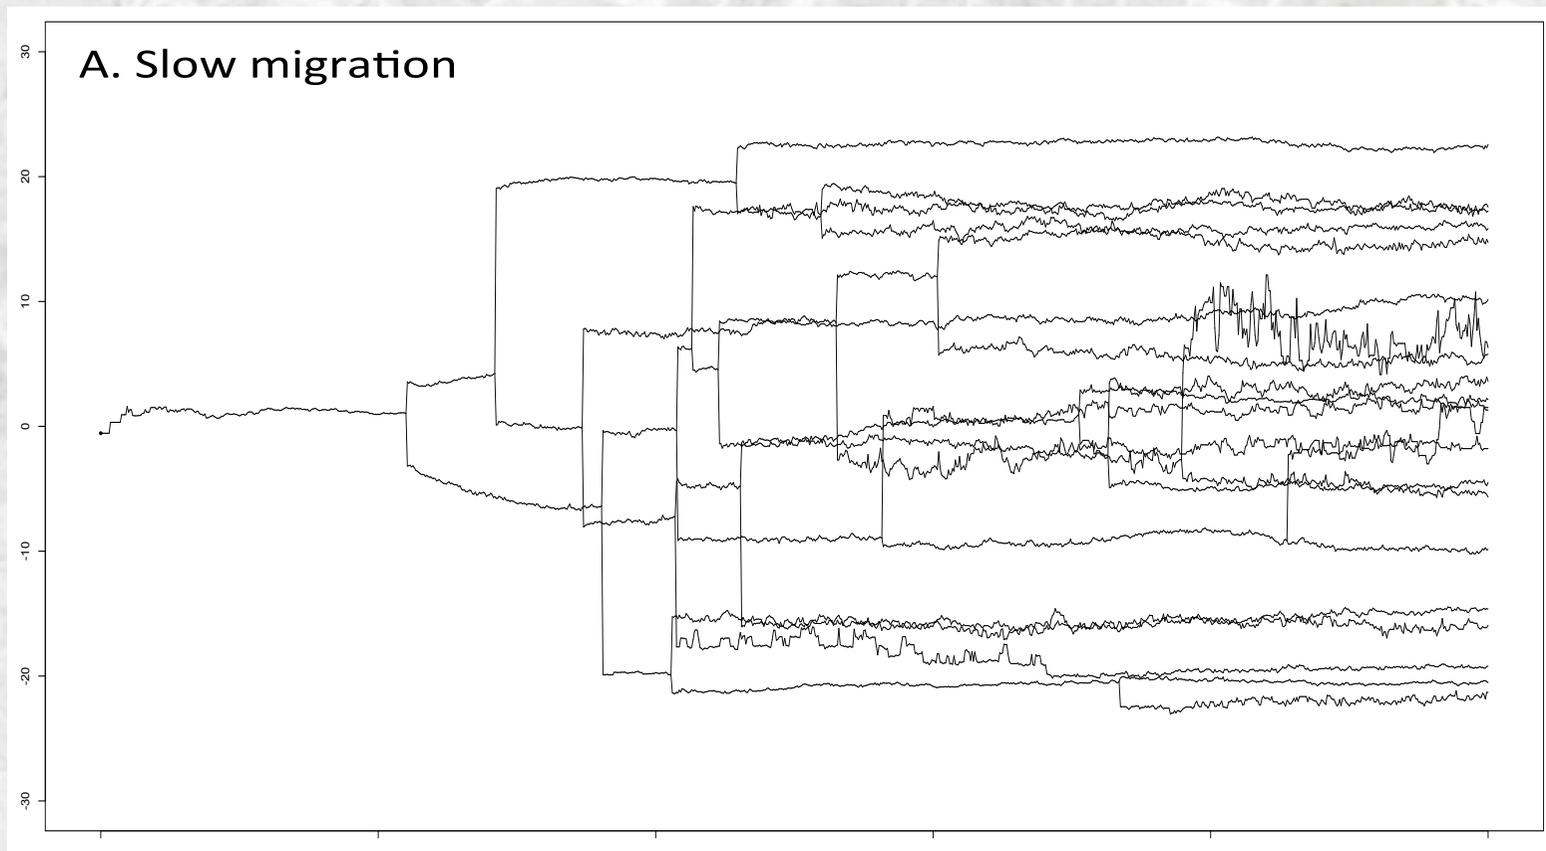

Random Fission

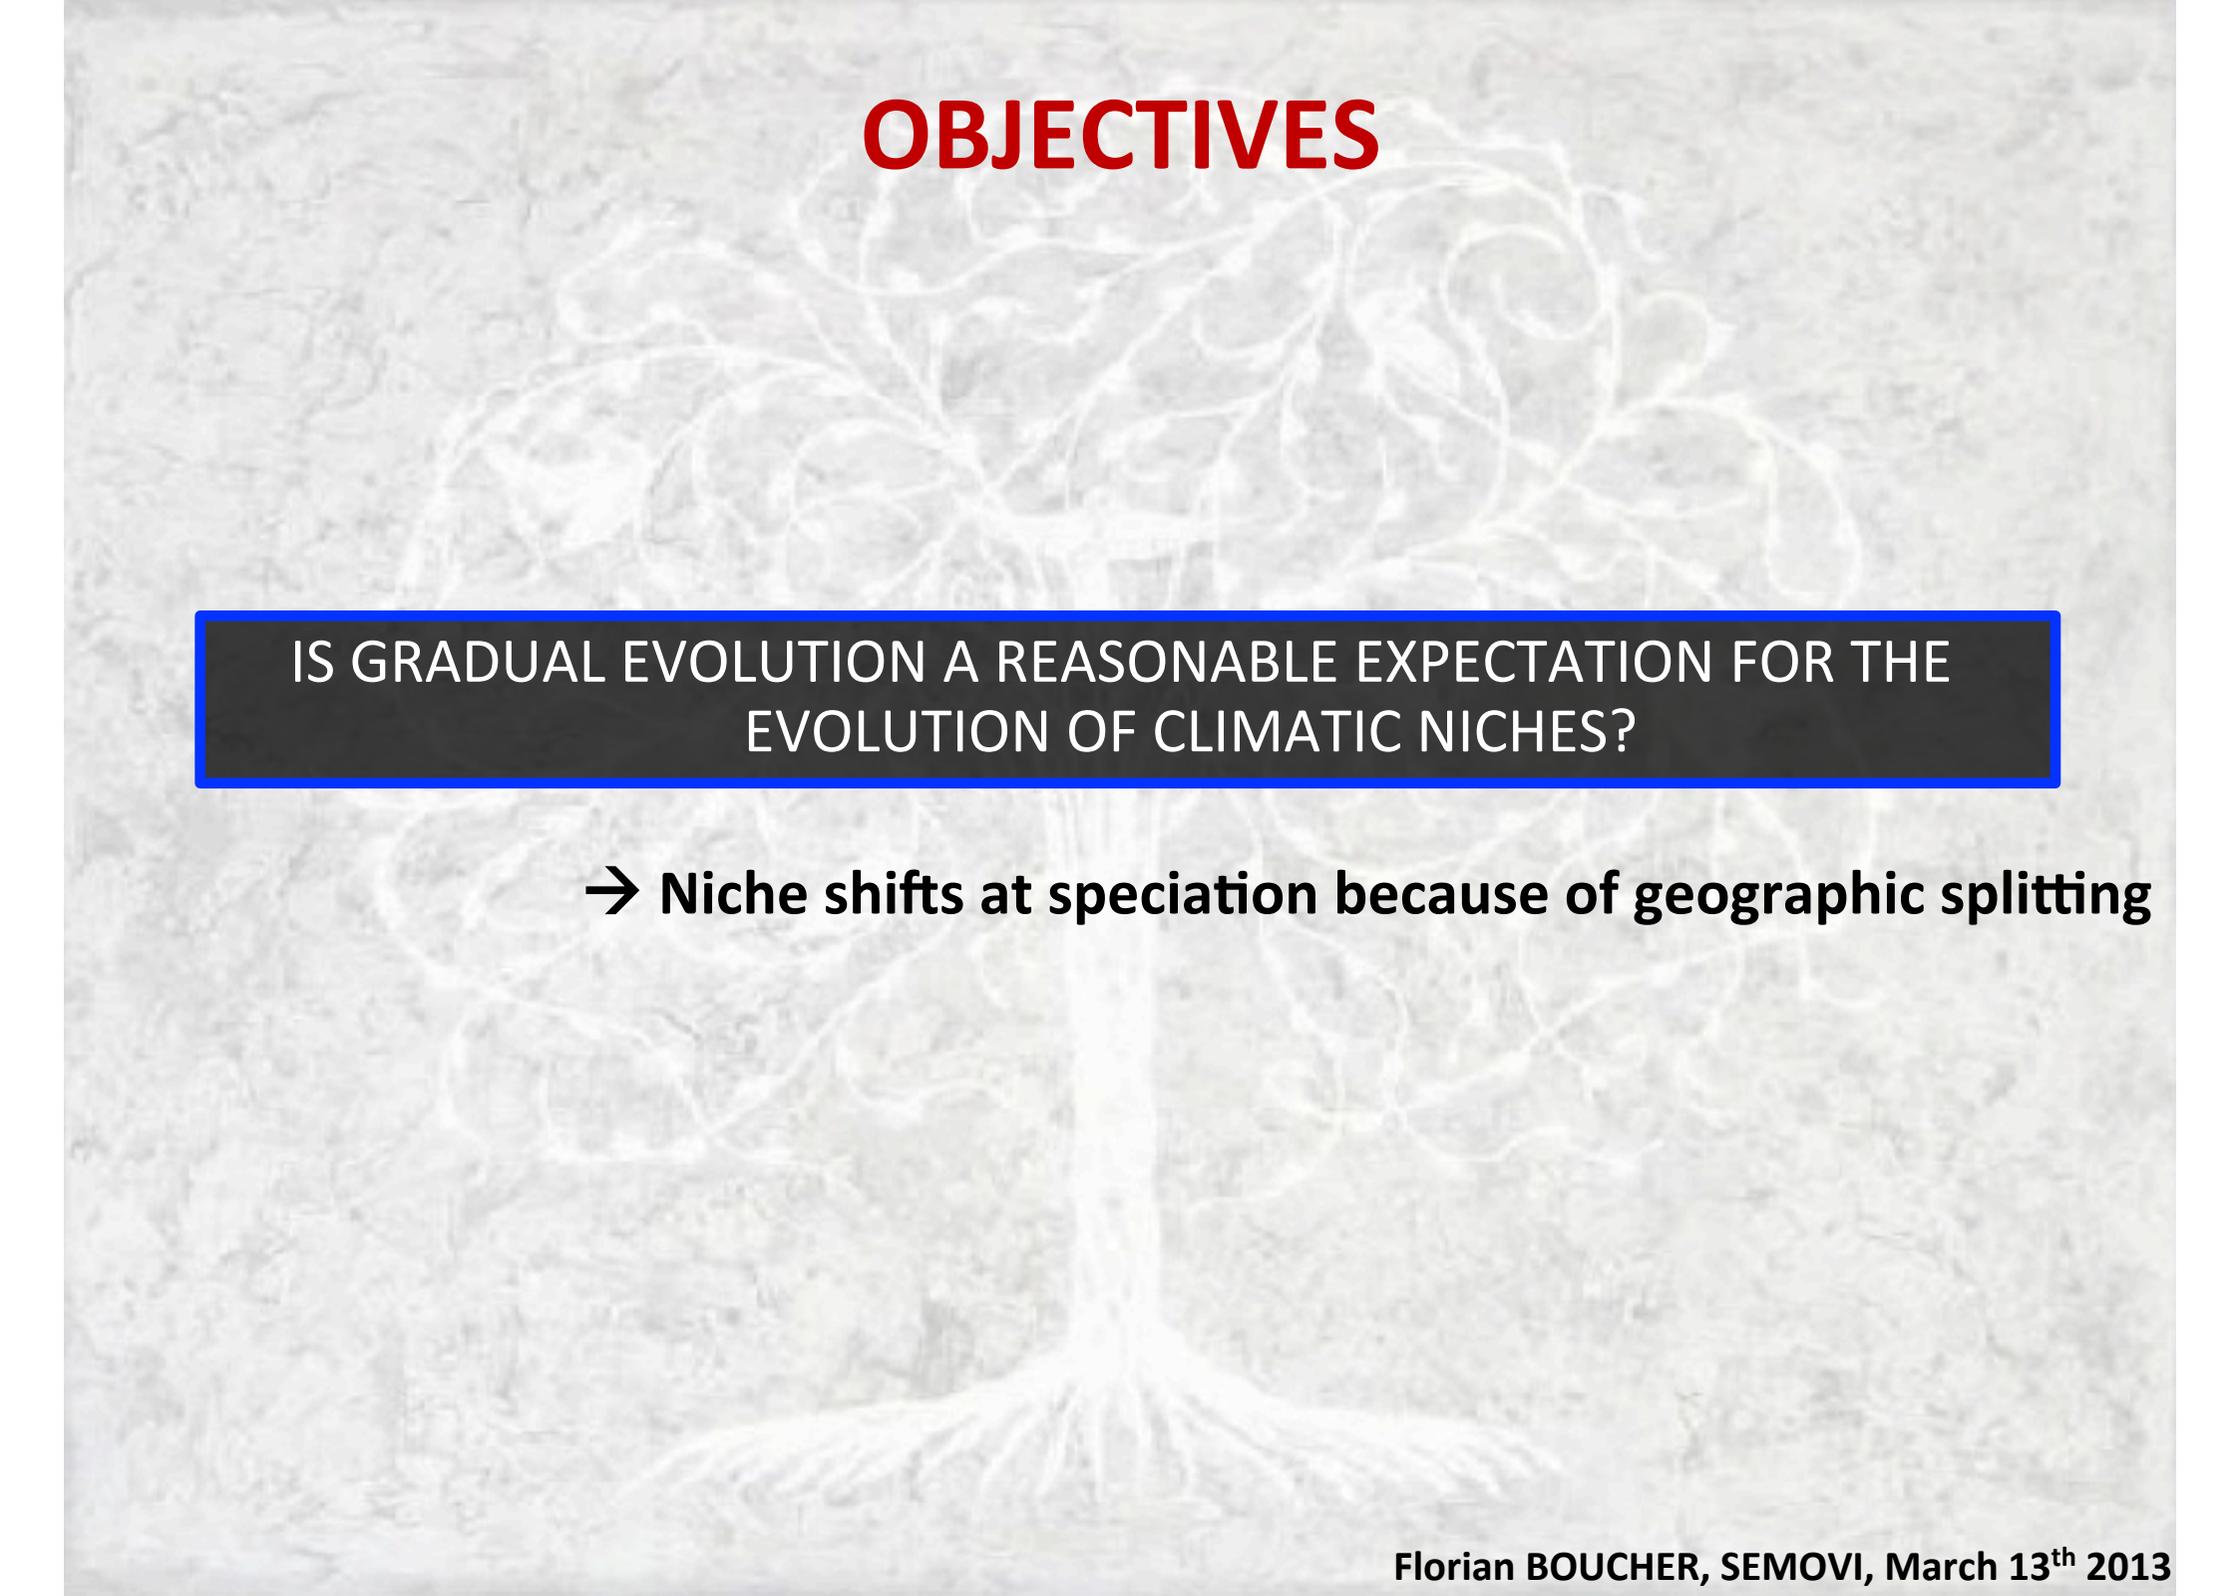

Vicariance

→ More very rare species and trees more imbalanced under Random Fission

# NICHE EVOLUTION DURING SIMULATIONS

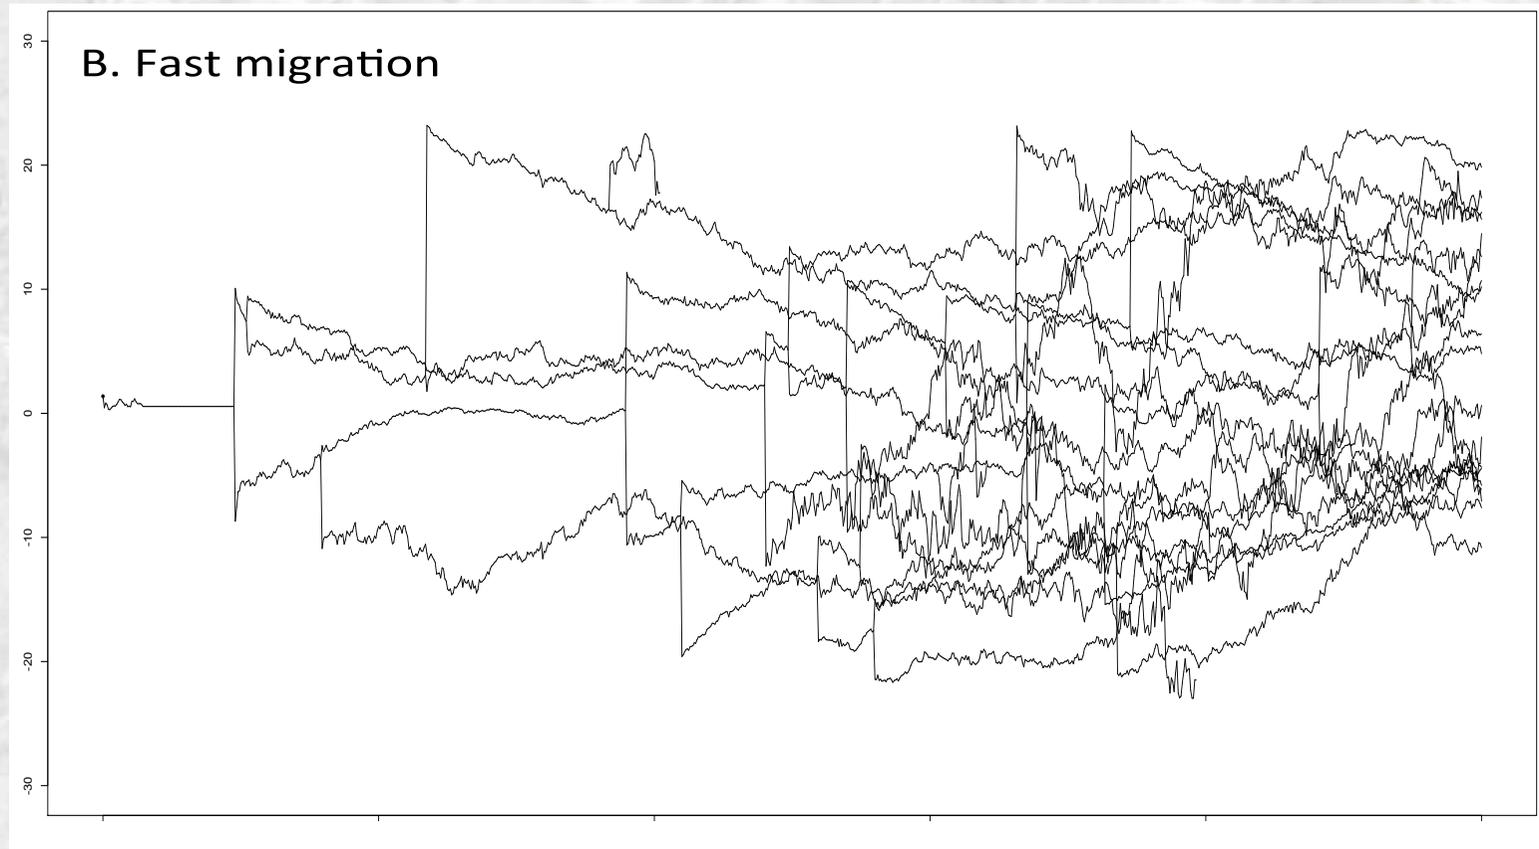

# OBJECTIVES

IS GRADUAL EVOLUTION A REASONABLE EXPECTATION FOR THE EVOLUTION OF CLIMATIC NICHES?

→ Niche shifts at speciation because of geographic splitting

# NICHE EVOLUTION DURING SIMULATIONS (2)

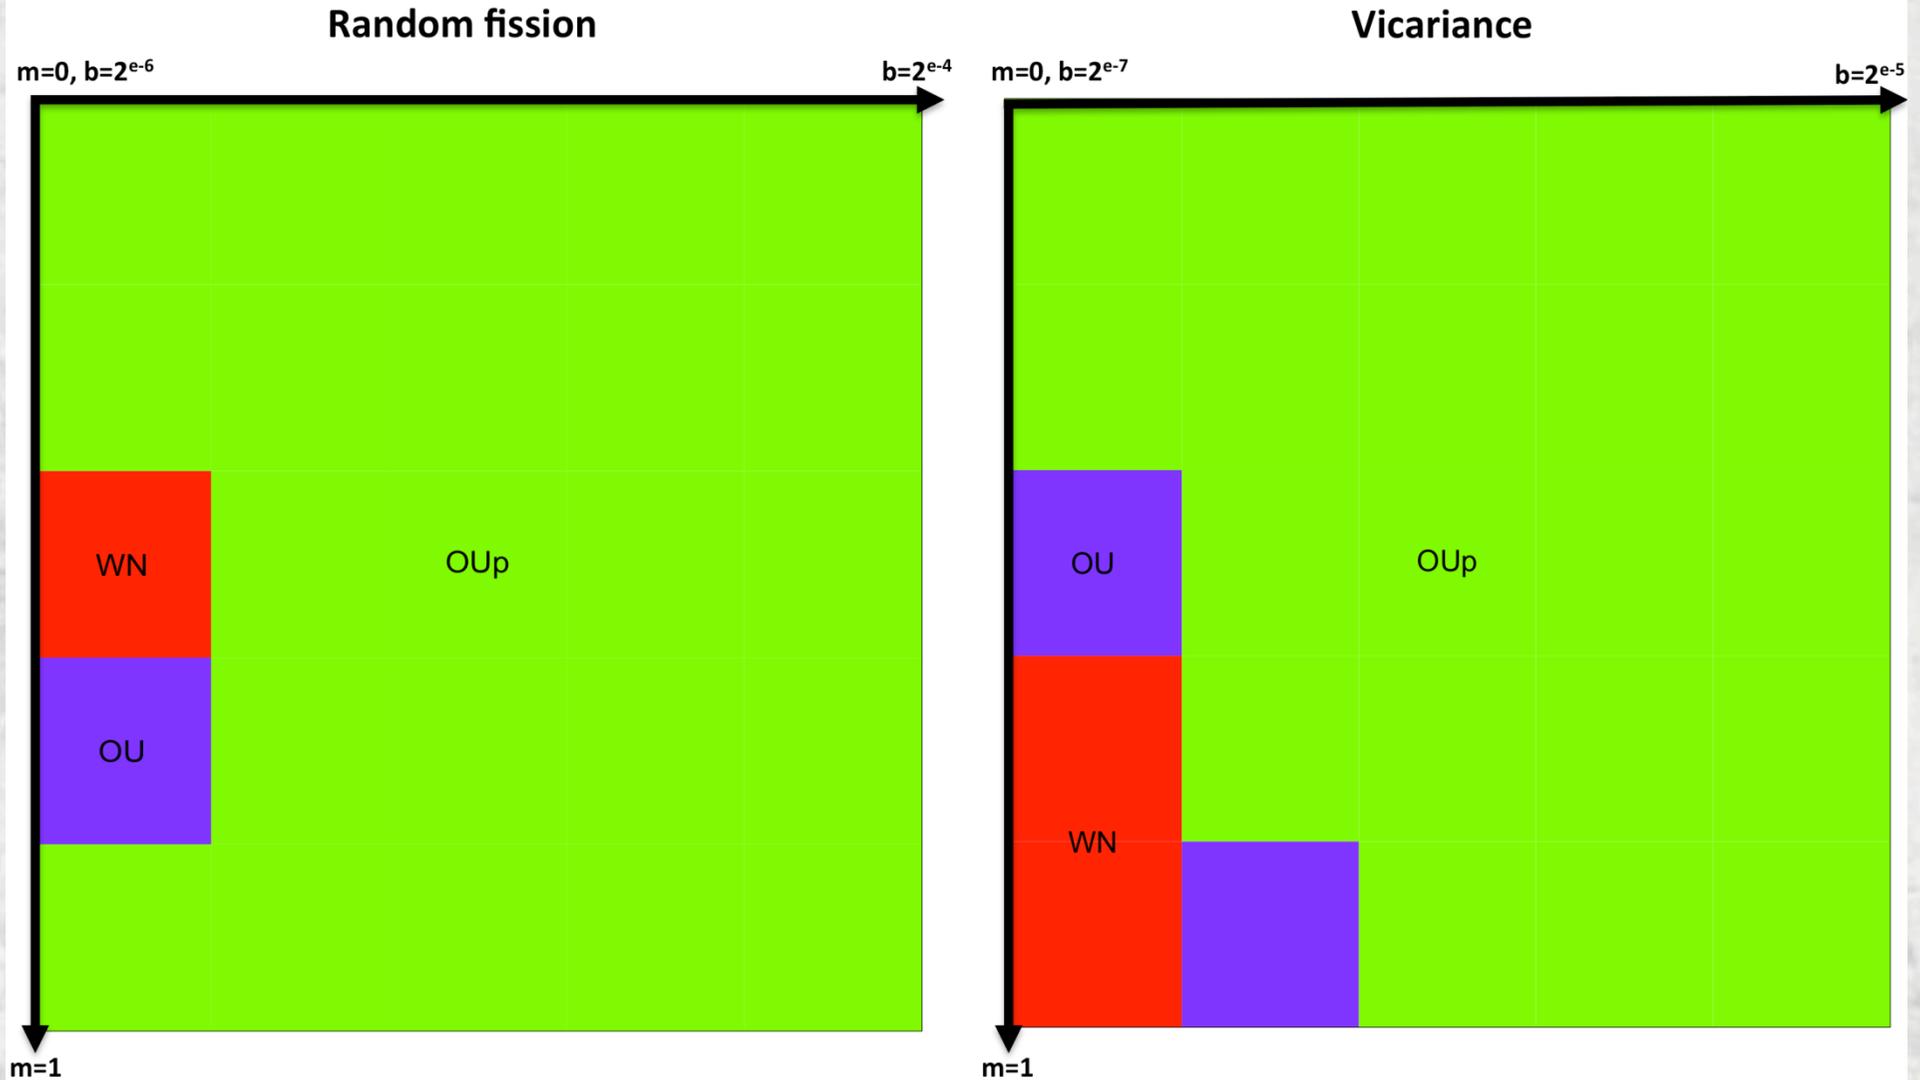

# OBJECTIVES

CAN CONSTRAINTS ON NICHE EVOLUTION ARISE SIMPLY THROUGH  
BOUNDED GEOGRAPHIC SPACE?

→ Niches are attracted towards the middle of the landscape  
because of the boundaries

# COMPARISON TO MACROEVOLUTIONARY MODELS

→ OUp = {constraints + punctualism} always the best

→ Brownian Motion often gets the worse fit

# OBJECTIVES

WHAT WOULD BE THE NEUTRAL EXPECTATION FROM A BIOGEOGRAPHIC POINT OF VIEW?

→ If niches evolved primarily through biogeographic processes and no physiological constraint were present, we would expect to see both punctualism and constraints

# CASE STUDY: *DIPROTODONTIA* IN AUSTRALIA

# CASE STUDY: *DIPROTODONTIA* IN AUSTRALIA

Various models fitted to the evolution of their mean annual temperature (AIC comparison):

	BM	KAPPA	OU	OUp	WN
<i>Diprotodontia</i>	2660.9	2663.0	1242.2	1240.9	3115.0

# CASE STUDY: *DIPROTODONTIA* IN AUSTRALIA

WHAT WOULD BE THE NEUTRAL EXPECTATION FROM A BIOGEOGRAPHIC POINT OF VIEW?

→ The neutral expectation should be punctualism + constraints.

# LIMITATIONS OF THE STUDY

## Processes are simplified:

- Migration in discrete steps
- Speciation is phenomenological

Climatic niches are more complex than a North-South gradient

Fundamental niches are not all equal of course...

# LIMITATIONS OF THE STUDY

## Processes are simplified:

- Migration in discrete steps
- Speciation is phenomenological

Climatic niches are more complex than a North-South gradient

Fundamental niches are not all equal of course...

→ Conclusions are mainly **qualitative**

→ Neutral Theory must be seen as a **first order approximation of reality**, on which to base more realistic models

# PERSPECTIVES FOR FUTURE STUDIES

Models with constraints may arise from various processes:

- Stabilizing selection, bounds in geographic space...

- **difficult to conclude on Phylogenetic Niche Conservatism** by contrasting simple models

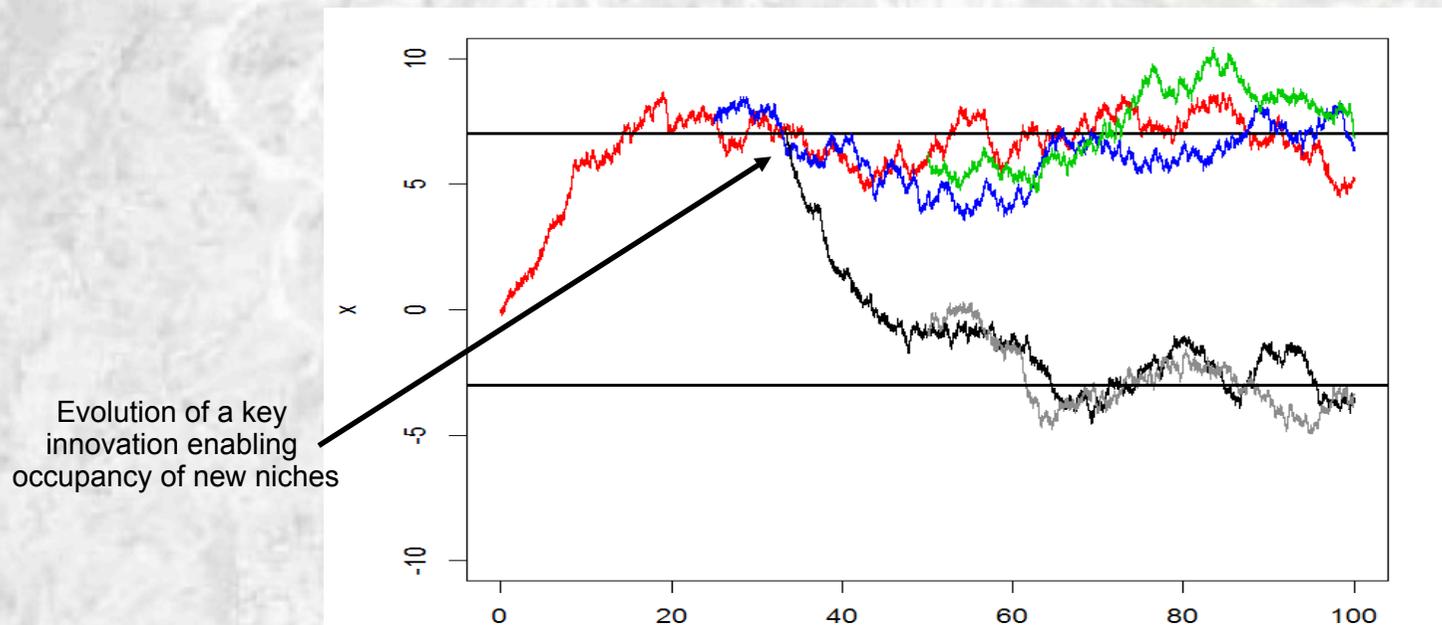

# PERSPECTIVES FOR FUTURE STUDIES

Models with constraints may arise from various processes:

- Stabilizing selection, bounds in geographic space...

→ **difficult to conclude on Phylogenetic Niche Conservatism** by contrasting simple models

More elaborate models, where niches depend on traits/distribution should be used:

→ **tools are already developed** (e.g. Beaulieu *et al.* 2012), let's use them!
